

XML Activity

Create an XML file called **student_record.xml**.

The file should have *record* as root element, and at least 2 *student* elements with *id* attributes.

The child elements of *student* should be:

firstname

lastname

major

gpa

Create a java class **StudentXML** that parses the **student_record** file and prints to the console the root element and each student element's attribute and child element text values (id, firstname, lastname, major, gpa). For example:

First Name: John

etc.

Zip and submit the **project** folder.
